# Synthesis, spectroscopic, dielectric, molecular docking and DFT studies of (3E)-3-(4-methylbenzylidene)-3,4-dihydro2 H -chromen-2-one: an anticancer agent 

T. Beena ${ }^{1}$, L. Sudha ${ }^{1}$, A. Nataraj ${ }^{1}$, V. Balachandran ${ }^{2}$, D. Kannan ${ }^{3}$ and M. N. Ponnuswamy ${ }^{4^{*}}$

#### Abstract

Background: Coumarin (2H-chromen-2-one) and its derivatives have a wide range of biological and pharmaceutical activities. They possess antitumor, anti-HIV, anticoagulant, antimicrobial, antioxidant, and anti-inflammatory activities. Synthesis and isolation of coumarins from different species have attracted the attention of medicinal chemists. Herein, we report the synthesis, molecular structure, dielectric, anticancer activity and docking studies with the potential target protein tankyrase. Results: Molecular structure of (3E)-3-(4-methylbenzylidene)-3,4-dihydro-2H-chromen-2-one (MBDC) is derived from quantum chemical calculations and compared with the experimental results. Intramolecular interactions, stabilization energies, and charge delocalization are calculated by NBO analysis. NLO property and dielectric quantities have also been determined. It indicates the formation of a hydrogen bonding between -OH group of alcohol and $\mathrm{C}=\mathrm{O}$ of coumarin. The relaxation time increases with the increase of bond length confirming the degree of cooperation and depends upon the shape and size of the molecules. The molecule under study has shown good anticancer activity against MCF-7 and HT-29 cell lines. Molecular docking studies indicate that the MBDC binds with protein. Conclusions: In this study, the compound (3E)-3-(4-methylbenzylidene)-3,4-dihydro-2H-chromen-2-one was synthesized and characterized by spectroscopic studies. The computed and experimental results of NMR study are tabulated. The dielectric relaxation studies show the existence of molecular interactions between MBDC and alcohol. Theoretical results of MBDC molecules provide the way to predict various binding sites through molecular modeling and these results also support that the chromen substitution is more active in the entire molecule. Molecular docking study shows that MBDC binds well in the active site of tankyrase and interact with the amino acid residues. These results are compared with the anti cancer drug molecule warfarin derivative. The results suggest that both molecules have comparable interactions and better docking scores. The results of the antiproliferative activity of MBDC and Warfarin derivative against MCF-7 breast cancer and HT-29 colon cancer cell lines at different concentrations exhibited signifcant cytotoxicity. The estimated half maximal inhibitory concentration (IC 50) value for MBDC and Warfarin derivative was 15.6 and $31.2 \mu \mathrm{~g} / \mathrm{ml}$, respectively. This enhanced cytotoxicity of MBDC in MCF-7 breast cancer and HT-29 colon cancer cell lines may be due to their efficient targeted binding and eventual uptake by the cells. Hence the compound MBDC may be considered as a drug molecule for cancer.

[^0]
## Background

Coumarin ( 2 H -chromen-2-one) is one of the important secondary metabolic derivatives which occurs naturally in several plant families. Coumarins are used as a fragrance in food and cosmetic products. Coumarins are widely distributed in the plant kingdom and are present in notable amounts in several species, such as Umbelliferae, Rutaceae and Compositae.
Coumarin and its derivatives have a wide range of biological and pharmaceutical activities. They possess antitumor [1], anti-HIV [2], anticoagulant [3], antimicrobial [4], antioxidant [5] and anti-inflammatory [6] activities. The antitumor activities of coumarin compounds have been extensively examined [7]. Synthesis and isolation of coumarins and its derivatives from different species have attracted the attention of medicinal chemists. The spectroscopic studies led to the beneficial effects on human health and their vibrational characteristics [8, 9].
Herein, we report the synthesis, the computed electronic structure and their properties in comparison with experimental FT-IR, FT Raman, UV and NMR spectra. Further, intra and inter molecular interactions, HOMOLUMO energies, dipole moment and NLO property have been determined. The dielectric studies confirm the molecular interactions and the strength of hydrogen bonding between the molecule and the solvent ethanol. In addition, anti-cancer activity against MCF-7 and HT-29 cell lines and molecular docking studies have also been performed.

## Experimental

## Preparation of MBDC

MBDC was synthesised from the mixture of methyl 2-[hydroxy(4-methylphenyl)methyl]prop-2-enoate ( $0.206 \mathrm{~g}, 1 \mathrm{mmol}$ ) and phenol ( $0.094 \mathrm{~g}, 1 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvent and allowed to cool at $0^{\circ} \mathrm{C}$. To this solution, concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}(0.098 \mathrm{~g}, 1 \mathrm{mmol})$ was added and stirred well at room temperature (Scheme 1). After completion of the reaction as indicated by TLC, the reaction mixture was neutralized with $1 \mathrm{M} \mathrm{NaHCO}_{3}$ and then extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The combined organic layers were washed with brine $(2 \times 10 \mathrm{ml})$ and dried over anhydrous sodium sulfate. The organic layer was evaporated and the residue was purified by column chromatography on silica
gel (100-200) mesh, using ethyl acetate and hexane (1:9) as solvents. The pure form of the title compound was obtained as a colorless solid ( 0.162 g ). Yield: $65 \%$, melting point: $132-134{ }^{\circ} \mathrm{C}$.

## Instrumentation

FTIR, FT-Raman, UV-Vis and NMR spectra were recorded using Bruker IFS 66 V spectrometer, FRA 106 Raman module equipped with Nd:YAG laser source, Beckman DU640 UV/Vis spectrophotometer and Bruker Bio Spin NMR spectrometer with $\mathrm{CDCl}_{3}$ as solvent, respectively. The dielectric constant ( $\varepsilon^{\prime}$ ) and dielectric loss $\left(\varepsilon^{\prime \prime}\right)$ at microwave frequency were determined by X-Band microwave bench and the dielectric constant $\left(\varepsilon_{\infty}\right)$ at optical frequency was determined by Abbe's refractometer equipped by $\mathrm{M} / \mathrm{s}$. Vidyut Yantra, India. The static dielectric constant $\left(\varepsilon_{0}\right)$ was measured by LCR meter supplied by M/s. Wissenschaijftlich Technische, Werkstatter, Germany. Anticancer activity for two cell lines was obtained from National Centre for Cell Sciences, Pune (NCCS).

## Cell line and culture

MCF-7 and HT-29 cell lines were obtained from National Centre for Cell Sciences, Pune (NCCS). The cells were maintained in Minimal Essential Medium supplemented with $10 \%$ FBS, penicillin ( $100 \mathrm{U} / \mathrm{ml}$ ), and streptomycin $(100 \mu \mathrm{~g} / \mathrm{ml})$ in a humidified atmosphere of $50 \mu \mathrm{~g} / \mathrm{ml} \mathrm{CO}_{2}$ at $37^{\circ} \mathrm{C}$.

## Reagents

MEM was purchased from Hi Media Laboratories, Fetal Bovine Serum (FBS) was purchased from Cistron laboratories trypsin, methylthiazolyl diphenyl-tetrazolium bromide (MTT) and dimethyl sulfoxide (DMSO) were purchased from (Sisco Research Laboratory Chemicals, Mumbai). All of other chemicals and reagents were obtained from Sigma Aldrich, Mumbai.

## In vitro assay for anticancer activity (MTT assay)

Cells ( $1 \times 10^{5} /$ well $)$ were plated in 24 -well plates and incubated at $37{ }^{\circ} \mathrm{C}$ with $5 \% \mathrm{CO}_{2}$ condition. After the cell reaches the confluence, the various concentrations of the samples were added and incubated for 24 h . After incubation, the sample was removed from the well and washed

Scheme 1 Reaction scheme showing the synthesis of the compound (MBDC)
with phosphate-buffered saline ( pH 7.4 ) or MEM without serum. $100 \mu \mathrm{l} /$ well $(5 \mathrm{mg} / \mathrm{ml})$ of $0.5 \% 3$-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyl-tetrazolium bromide (MTT) was added and incubated for 4 h . After incubation, 1 ml of DMSO was added in all the wells. The absorbance at 570 nm was measured with UV-Spectrophotometer using DMSO as the blank. The \%cell viability was calculated using the following formula:

$$
\% \text { cell viability }=\frac{\mathrm{A} 570 \text { of treated cells }}{\mathrm{A} 570 \text { of control cells }} \times 100
$$

## Computational methods

Electronic structure and optimized geometrical parameters were calculated by density functional theory (DFT) using Gaussian 09W software package [10] with B3LYP/6-31 + G(d,p) basis set method and Gauss-View molecular visualization program package on a personal computer [11]. Vibrational normal mode wavenumbers of MBDC were derived with IR intensity and Raman intensity. The entire vibrational assignments were executed on the basis of the potential energy distribution (PED) of vibrational modes from VEDA 4 program and calculated with scaled quantum mechanical (SQM) method. The X-ray crystal structure of tankyrase (PDB ID: 4L2K) [12] was obtained from Protein Data Bank (PDB). All docking calculations were performed using induced-fit-docking module of Schrödinger suite [13].

## Results and discussion

## Molecular geometry

The optimized molecular structure of MBDC along with the numbering of atoms is shown in Fig. 1. The calculated
and experimental bond lengths and bond angles are presented in Table 1. The molecular structure of the compound is obtained from Gaussian 09W and GAUSSVIEW program. The optimized structural parameters (bond lengths and bond angles) calculated by DFT/B3LYP with $6-31+G(d, p)$ basis set are compared with experimentally available X-ray data for benzylidene [14] and coumarin [15].
From the structural data, it is observed that the various $\mathrm{C}-\mathrm{C}$ bond distances calculated between the rings 1 and 2 and $\mathrm{C}-\mathrm{H}$ bond lengths are comparable with that of the experimental values of benzylidene and coumarins. The influence of substituent groups on $\mathrm{C}-\mathrm{C}$ bond distances of ring carbon atoms seems to be negligibly small except that of C3-C4 (1.404 $\AA$ ) bond length which is slightly longer than the normal value.
The calculated bond lengths of $\mathrm{C} 8-\mathrm{C} 13$ and $\mathrm{C} 4-$ C20, are 1.491 and $1.509 \AA$ in the present molecule and comparable with the experimental values of 1.491 and $1.499 \AA$. The experimental value for the bond $\mathrm{C} 13-\mathrm{O} 7$ ( $1.261 \AA$ ) is little longer than the calculated value $1.211 \AA$. The $\mathrm{C}-\mathrm{H}$ bond length variations are due to the different substituent's in the ring and other atoms [16]. The hyperconjugative interaction effect leads to the deviation of bond angle for $\mathrm{C} 10-\mathrm{C} 11-\mathrm{O} 12$ (121.79 $)$ from the standard value (120.8 ${ }^{\circ}$.

## Vibrational spectra

The title compound possesses $C_{s}$ point group symmetry and the available 93 normal modes of vibrations are distributed into two types, namely $A^{\prime}$ (in-plane) and $A^{\prime \prime}$ (out-plane). The irreducible representation for the $\mathrm{C}_{\mathrm{s}}$

${ }^{\text {a }}$ X-ray data from Refs. [14] and [15]
symmetry is given by $\Gamma_{\mathrm{Vib}}=63 A^{\prime}+30 A^{\prime \prime}$. All the vibrations are active in both IR and Raman spectra. Vibrational assignments have been carried out from FT-IR (Fig. 2) and FT-Raman (Fig. 3) spectra. The theoretically predicted wavenumbers along with their PED values are presented in Table 2. The fundamental vibrational modes are also characterized by their PED. The calculated wavenumbers are in good agreement with experimental wavenumbers.

## Carbon-hydrogen vibrations

The $\mathrm{C}-\mathrm{H}$ stretching vibrations are expected to appear at $3100-2900 \mathrm{~cm}^{-1}$ [17] with multiple weak bands. The four hydrogen atoms left around each benzene ring give rise to a couple of $\mathrm{C}-\mathrm{H}$ stretching, $\mathrm{C}-\mathrm{H}$ in-plane bending and $\mathrm{C}-\mathrm{H}$ out-of-plane bending vibrations. In MBDC, the calculated wavenumbers at 2936, 2945, 2962, 2989, 2993, 2999, 3007, 3018 and $3101 \mathrm{~cm}^{-1}$ are assigned to $\mathrm{C}-\mathrm{H}$ stretching modes which show good agreement with the literature values [18]. The C-H in-plane bending vibrations occur in the region of $1390-990 \mathrm{~cm}^{-1}$. The vibrational assignments at 900,990 and $1000 \mathrm{~cm}^{-1}$ (Fig. 3) occur due to the effect of $\mathrm{C}-\mathrm{H}$ in-plane bending vibrations. The calculated wavenumbers at $889,903,923,951$, 968, 992, 1011, 1029 and $1042 \mathrm{~cm}^{-1}$ are due to $\mathrm{C}-\mathrm{H}$ inplane bending vibrations which show good agreement with recorded spectral values.
The out-of-plane bending of ring $\mathrm{C}-\mathrm{H}$ bonds occur below $900 \mathrm{~cm}^{-1}$ [19]. In MBDC, the $\mathrm{C}-\mathrm{H}$ out-of-plane bending vibrations are observed at 540, 575, 600 and $725 \mathrm{~cm}^{-1}$ which are compared with the computed values at $527,540,572,601,633,669,689,716$ and $723 \mathrm{~cm}^{-1}$.

## Carbon-carbon vibrations

The ring $\mathrm{C}=\mathrm{C}$ and $\mathrm{C}-\mathrm{C}$ stretching vibrations, known as semicircle stretching modes, usually occur in the region of $1625-1400 \mathrm{~cm}^{-1}$ [20]. Generally, these bands are of variable intensity and observed at $1625-1590 \mathrm{~cm}^{-1}, 1590-$ $1575 \mathrm{~cm}^{-1}, 1540-1470 \mathrm{~cm}^{-1}, 1465-1430 \mathrm{~cm}^{-1}$ and 1380$1280 \mathrm{~cm}^{-1}$ [21]. In MBDC, the aromatic C-C stretching vibrations are observed at $1209 \mathrm{~cm}^{-1}$ (Fig. 2). The $\mathrm{C}-\mathrm{C}$ stretching vibrations are assigned at 1432 and $1500 \mathrm{~cm}^{-1}$ in FT-IR and at 1540 and $1600 \mathrm{~cm}^{-1}$ in FT-Raman spectrum. These values perfectly match with the calculated wavenumbers, $1306-1615 \mathrm{~cm}^{-1}$ (mode no. 64-78). The $\mathrm{C}-\mathrm{C}-\mathrm{C}$ in-plane bending vibrations are observed at $810 \mathrm{~cm}^{-1}$ in FT-IR spectrum and at 850 and $875 \mathrm{~cm}^{-1}$ in FT-Raman spectrum. The calculated values are $811-$ $872 \mathrm{~cm}^{-1}$ (mode no: $33-40$ ). The $\mathrm{C}-\mathrm{C}-\mathrm{C}$ out-of-plane bending vibrations appeared at 350 and $400 \mathrm{~cm}^{-1}$ in FTRaman spectrum and the corresponding calculated wavenumbers at $255-453 \mathrm{~cm}^{-1}$ (mode no: $11-18$ ) show good agreement with the literature values [16]. These observed wavenumbers show that the substitutions in the benzene ring affect the ring modes of vibrations to a certain extent.

## C-O vibrations

The C-O stretching vibrations are observed at 1300$1200 \mathrm{~cm}^{-1}$ [22]. In the present molecule, the $\mathrm{C}-\mathrm{O}$ stretching is observed at $1189 \mathrm{~cm}^{-1}$ in FT-IR spectrum and the calculated vibration is at 1153 and $1190 \mathrm{~cm}^{-1}$. The $\mathrm{C}-\mathrm{O}$ in-plane bending vibration is observed at

Fig. 2 a Experimental and $\mathbf{b}$ predicted FT-IR spectra of MBDC
$750 \mathrm{~cm}^{-1}$ in FT-IR matches with the theoretical value of $748 \mathrm{~cm}^{-1}$. In this molecule, the peak observed at $500 \mathrm{~cm}^{-1}$ in FT-Raman and $506 \mathrm{~cm}^{-1}$ in FT-IR are attributed to $\mathrm{C}-\mathrm{O}$ out-of-plane bending vibrations. The $\mathrm{C}=\mathrm{O}$ stretching vibration is generally observed at $1800-1600 \mathrm{~cm}^{-1}$ [23]. In MBDC, the $\mathrm{C}=\mathrm{O}$ stretching is observed at $1616 \mathrm{~cm}^{-1}$ in FT-IR and at $1690 \mathrm{~cm}^{-1}$ in FTRaman spectrum. This peak matches with the calculated value ( $1692 \mathrm{~cm}^{-1}$ ).

## $\mathrm{CH}_{2}$ vibrations

The asymmetric $\mathrm{CH}_{2}$ stretching vibrations are generally observed between 3000 and $2800 \mathrm{~cm}^{-1}$, while the symmetric stretch appears between 2900 and $2800 \mathrm{~cm}^{-1}$ [24]. In MBDC, the $\mathrm{CH}_{2}$ asymmetric and symmetric stretching vibrations are calculated at 2809 and $2801 \mathrm{~cm}^{-1}$ respectively. The asymmetric bending is calculated at
$1243 \mathrm{~cm}^{-1}$. In FT-IR spectrum the symmetric bending vibration is observed at $1215 \mathrm{~cm}^{-1}$ and calculated at $1231 \mathrm{~cm}^{-1}$. The in-plane $\mathrm{CH}_{2}$ bending vibration is observed at $1000 \mathrm{~cm}^{-1}$ in FT-Raman spectrum and the calculated vibration is at $1053 \mathrm{~cm}^{-1}$. The out-of-plane $\mathrm{CH}_{2}$ bending vibration is calculated at $1061 \mathrm{~cm}^{-1}$. The above results suggest that the observed frequencies are in good agreement with calculated in-plane and out-ofplane modes.

## $\mathrm{CH}_{3}$ vibrations

There are nine fundamental modes associated with each $\mathrm{CH}_{3}$ group. In aromatic compounds, the $\mathrm{CH}_{3}$ asymmetric and symmetric stretching vibrations are expected in the range of $2925-3000 \mathrm{~cm}^{-1}$ and $2905-2940 \mathrm{~cm}^{-1}$, respectively [25]. In $\mathrm{CH}_{3}$ antisymmetric stretching mode, two $\mathrm{C}-\mathrm{H}$ bonds are expanding while the third one is

Fig. 3 a Experimental and $\mathbf{b}$ predicted FT-Raman spectra of MBDC
contracting. In symmetric stretching, all the three $\mathrm{C}-\mathrm{H}$ bonds are expanding and contracting in-phase. In MBDC, the assigned vibrations at 2911,2889 and $2863 \mathrm{~cm}^{-1}$ represent asymmetric and symmetric $\mathrm{CH}_{3}$ stretching vibrations [26]. The $\mathrm{CH}_{3}$ symmetric bending vibrations are observed at $1250 \mathrm{~cm}^{-1}$ in FT-Raman spectrum and calculated at $1250 \mathrm{~cm}^{-1}$ which are in good agreement with experimental and theoretical vibrations. The $\mathrm{CH}_{3}$ asymmetric bending vibrations are observed at $1261 \mathrm{~cm}^{-1}$ and calculated at 1260 and $1287 \mathrm{~cm}^{-1}$ match with the experimental values. The inplane $\mathrm{CH}_{3}$ bending vibration is assigned at $1075 \mathrm{~cm}^{-1}$ in FT-Raman and calculated at $1072 \mathrm{~cm}^{-1}$ in B3LYP and out-of-plane $\mathrm{CH}_{3}$ bending vibration is observed at $1100 \mathrm{~cm}^{-1}$ in FT-Raman and calculated at $1104 \mathrm{~cm}^{-1}$. Predicted wavenumbers derived from B3LYP/6-31 + G(d,p) method synchronise well with those of the experimental observations.

## HOMO-LUMO analysis

The most important orbitals in the molecule is the frontier molecular orbitals, called highest occupied molecular orbital (HOMO) and lowest unoccupied molecular orbital (LUMO). These orbitals determine the way the molecule interacts with other species. The

HOMO-LUMO energy gap of MBDC is shown in Fig. 4. The HOMO ( $-51.0539 \mathrm{kcal} / \mathrm{mol}$ ) is located over the coumarin group and LUMO $(-49.0962 \mathrm{kcal} / \mathrm{mol})$ is located over the ring; the $\mathrm{HOMO} \rightarrow$ LUMO transition implies the electron density transfer to ring benzylidene. The calculated self-consistent field (SCF) energy of MBDC is $-506,239.7545 \mathrm{kcal} / \mathrm{mol}$. The frontier orbital gap is found to be $E=-101.9576 \mathrm{kcal} / \mathrm{mol}$ and this negative energy gap confirms the intramolecular charge transfer. This proves the non-linear optical (NLO) activity of the material [27]. A molecule with a small frontier molecular orbital is more polarizable and generally associated with high chemical reactivity, low kinetic stability termed as soft molecule [28]. The low value of frontier molecular orbital in MBDC makes it more reactive and less stable.

## NBO analysis

Natural bond orbital (NBO) of the molecule explains the molecular wave function in terms of Lewis structures, charge, bond order, bond type, hybridization, resonance, donor-acceptor interactions, etc. NBO analysis has been performed on MBDC to elucidate the intramolecular, rehybridization and also the interaction which

[^1]

Fig. 4 The calculated frontiers energies of MBDC
will weaken the bond associated with the anti-bonding orbital. Conversely, an interaction with a bonding pair will strengthen the bond.
The corresponding results are presented in Tables 3 and 4. The intramolecular interaction between lone pair of O 27 with antibonding $\mathrm{C} 13-\mathrm{O} 12$ results in a stabilized energy of $35.64 \mathrm{kcal} / \mathrm{mol}$. The most important interaction in MBDC is between the $\mathrm{LP}(2) \mathrm{O} 12$ and the antibonding $\mathrm{C} 13-\mathrm{O} 27$. This results in a stabilization energy $41.74 \mathrm{kcal} / \mathrm{mol}$ and denotes larger delocalization. The valence hybrid analysis of NBO shows that the region of electron density distribution mainly influences the polarity of the compound. The maximum electron density on the oxygen atom is responsible for the polarity of the molecule. The p-character of oxygen lone pair orbital $\mathrm{LP}(2) \mathrm{O} 27$ and $\mathrm{LP}(2) \mathrm{O} 12$ are 99.66 and 99.88, respectively. Thus, a very close pure p-type lone pair orbital participates in the electron donation in the compound.

## Mulliken charges

The Mulliken atomic charges of MBDC were calculated by B3LYP/6-31 + G (d,p) level theory (Table 5). It is important to mention that the atoms $\mathrm{C} 1, \mathrm{C} 2, \mathrm{C} 4, \mathrm{C} 7, \mathrm{C} 10, \mathrm{H} 18, \mathrm{H} 19$,

O27 of MBDC exhibit positive charges, whereas the atoms C3, C5, C6, C11, O12 exhibit negative charges. The maximum negative and positive charge values are -0.95788 for C11 and 0.90500 for C10 in the molecule, respectively.

## UV-Visible analysis

Theoretical UV-Visible spectrum (Table 6) of MBDC was derived by employing polarizable continuum model (PCM) and TD-DFT method with B3LYP/6-31 + G(d,p) basis set and compared with experimentally obtained UV-Visible spectrum (Fig. 5). The spectrum shows the peaks at 215 and 283 nm whereas the calculated absorption maxima values are noted at 223, 265 and 296 nm in the solvent of ethanol. These bands correspond to one electron excitation from HOMO-LUMO. The band at 223 and 265 nm are assigned to the dipole-allowed $\sigma \rightarrow \sigma^{*}$ and $\pi \rightarrow \pi^{*}$ transitions, respectively. The strong transitions are observed at $2.414 \mathrm{eV}(215 \mathrm{~nm})$ with $f=0.0036$ and at $2.268 \mathrm{eV}(283 \mathrm{~nm})$ with $f=0.002$.

## Molecular electrostatic potential

Molecular electrostatic potential at the surface are represented by different colours (inset in Fig. 5). Red

colour indicates electronegative character responsible for electrophilic attack, blue colour indicates positive region representing nucleophilic attack and green colour represents the zero potential. The electrostatic potential increases in the order red < orange < yellow < green < blue [29]. The mapped electrostatic potential surface of the molecule shows that atoms O27 and O12 of chromen possess negative potential and all H atoms have positive potential. The same regions are identified in the Mulliken charges also.

## Hyper polarizability

On the basis of the finite-field approach, using B3LYP/6$31+G(d, p)$ basis set, the first hyperpolarizability $(\beta)$, dipole moment $(\mu)$ and polarizability $(\alpha)$ for MBDC are calculated and compared with urea (Table 7) [30]. The dipole moment of MBDC is 1.6941 times greater than the magnitude of urea ( $\mu_{\text {tot }}$ of urea is 3.2705 D ) and the first hyperpolarizability is 1.51 times greater than the magnitude of urea ( $\beta_{\text {tot }}$ of urea is $3.7472 \times 10^{-31} \mathrm{esu}$ ). Urea is the standard NLO crystal reported earlier [31] so that a direct comparison was made.

## Dielectric studies

The experimental data of $\varepsilon_{0}, \varepsilon^{\prime}, \varepsilon_{\infty}$ and $\tau$ of MBDC in ethanol at various concentrations are presented in Table 8. The static and microwave dielectric constants decrease with increasing concentration of the compound. This shows a weak interaction exists between the molecule and the solvent at low frequencies. Optical dielectric constant increases with increasing solute concentration which leading to a strong interaction between MBDC and ethanol at high frequency. It indicates the formation of a hydrogen bonding between -OH group of alcohol and $\mathrm{C}=\mathrm{O}$ of coumarin. The relaxation time increases with the increase of bond length confirming the degree of cooperation, shape and size of the molecule [32].

## NMR study

The characterization of MBDC was further enhanced by the study of ${ }^{1} \mathrm{H}$ NMR method. The computed ${ }^{13} \mathrm{C}$ NMR and ${ }^{1} \mathrm{H}$ NMR chemical shifts and experimental ${ }^{1} \mathrm{H}$ NMR are compiled in Table 9. The experimental ${ }^{1} \mathrm{H}$ NMR spectrum in $\mathrm{CDCl}_{3}$ solution is shown in Fig. 6. The relevant difference of ${ }^{1} \mathrm{H}$ NMR chemical shifts calculated

by GIAO/B3LYP method is: $0.06(\mathrm{H} 31), 0.17(\mathrm{H} 26)$ and 0.19 (H24). The maximum deviation from experimental value is responded to be 0.19 ppm for H 24 atom [33]. Overall the calculated values agree with the experimental chemical shift values and the slight deviations may be due to the influence of proton exchange, hydrogen bond and solvent effect in complex real systems. The results of ${ }^{13} \mathrm{C}$ NMR chemical shift of the MBDC compound is reliable for the interpretation of spectroscopic parameters. The C1 and C2 atoms of the compound are attached with the electron releasing group and hence they are more electron donating than C15. This causes more shielding
at C 1 and C 2 positions and hence the chemical shift values are lesser.

## Molecular docking studies

Glide docking was used to study the binding orientations and affinities of MBDC with tankyrase as target protein (Fig. 7). Tankyrases are ADP-ribosyltransferases that play key roles in various cellular pathways, including the regulation of cell proliferation, and thus they are promising drug targets for the treatment of cancer [12]. The keto atom in MBDC interacts with SER1068 and GLY1032 at distances of 3.17 and $2.91 \AA$, respectively (Table 10). This

## Anticancer activity

The results of the antiproliferative activity of MBDC and Warfarin derivative against MCF-7 breast cancer and HT-29 colon cancer cell lines at different concentrations (7.8, 15.6, 31.2, 62.5, 125, 250, 500 and $1000 \mu \mathrm{~g} /$ ml ) for 24 h , and cell proliferation was measured by a standard MTT assay. As shown in Figs. 8a, b and 9a, b, MCF-7 and HT-29 cells exposed to MBDC and Warfarin derivative exhibited significant cytotoxicity in the dose dependent manner after 24 h treatment. The estimated half maximal inhibitory concentration (IC 50) value for MBDC and Warfarin derivative was 15.6 and $31.2 \mu \mathrm{~g} /$ ml respectively. This enhanced cytotoxicity of MBDC in MCF-7 breast cancer and HT-29 colon cancer cell lines may be due to their efficient targeted binding and eventual uptake by the cells.

## Conclusion

The vibrational and molecular structure analysis have been performed based on the quantum mechanical approach using DFT calculations. The difference in the observed and scaled wavenumber values of most fundamentals is very small. Therefore, the assignments made using DFT theory with experimental values seem to be correct. The geometrical structure shows a little distortion due to the substitution of methyl benzylidene and chromen group in the benzene.
The chromen group substitution plays an important role with its characteristic peaks compared in both experimental and theoretical FTIR and FT-Raman spectra. The MEP map shows negative potential sites on O27 and O12 of chromen and positive potential sites on all H atoms which are responsible for electrophilic and nucleophilic attacks, respectively.

Fig. 6 Experimental ${ }^{1} \mathrm{H}$ NMR spectrum of MBDC

In addition, HOMO and LUMO orbitals are in agreement with MEP. The results indicate that the title compound is found to be useful to bond metallicity and inter molecular interaction. The NBO analysis explains the large delocalization of charge in the molecule. The predicted NLO properties are compared with that of urea and the title compound seems to be a good candidate of second-order NLO materials.

Molecular docking study shows that MBDC binds well in the active site of tankyrase and interact with the amino acid residues. These results are compared with the anti cancer drug molecule of warfarin derivative. The results suggest that both the molecules have comparable interactions and better docking scores. The results of the antiproliferative activity of MBDC and Warfarin derivative against MCF-7 breast cancer and HT-29 colon cancer

drug molecule for cancer. The dielectric relaxation studies show the existence of molecular interactions between MBDC and alcohol. The NMR spectrum confirms the molecular structure of the compound.

## Authors' contributions

TB proposed the work, carried out the DFT studies, dielectric, NMR and anticancer studies, arranged the results and drafted the manuscript under the guidance of LS. Spectroscopic studies carried out by AN under the guidance of VB. DK synthesized the title compound. Molecular docking, manuscript revision and final shape were done by MNP. All authors read and approved the final manuscript.

MNP thanks UGC, New Delhi for the financial support in the form of UGCEmeritus Fellowship. We wish to thank (BIF) at CAS in Crystallography and Biophysics, University of Madras, Chennai-25.

## Competing interests

This is the characterization study which provides the needed information to prove that the molecule MBDC competes with Warfarin derivative as an anticancer agent.
