Validated spectrophotometric methods for determination of Alendronate sodium in tablets through nucleophilic aromatic substitution reactions

Mohamed I Walash, Mohamed E-S Metwally, Manal Eid and Rania N El-Shaheny*

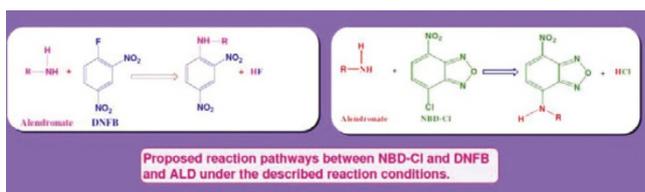

Abstract

Background: Alendronate (ALD) is a member of the bisphosphonate family which is used for the treatment of osteoporosis, bone metastasis, Paget's disease, hypocalcaemia associated with malignancy and other conditions that feature bone fragility. ALD is a non-chromophoric compound so its determination by conventional spectrophotometric methods is not possible. So two derivatization reactions were proposed for determination of ALD through the reaction with 4-chloro-7-nitrobenzo-2-oxa-1,3-diazole (NBD-Cl) and 2,4-dinitrofluorobenzene (DNFB) as chromogenic derivatizing reagents.

Results: Three simple and sensitive spectrophotometric methods are described for the determination of ALD. Method I is based on the reaction of ALD with NBD-Cl. Method II involved heat-catalyzed derivatization of ALD with DNFB, while, Method III is based on micellar-catalyzed reaction of the studied drug with DNFB at room temperature. The reactions products were measured at 472, 378 and 374 nm, for methods I, II and III, respectively. Beer's law was obeyed over the concentration ranges of 1.0-20.0, 4.0-40.0 and 1.5-30.0 $\mu\text{g/mL}$ with lower limits of detection of 0.09, 1.06 and 0.06 $\mu\text{g/mL}$ for Methods I, II and III, respectively. The proposed methods were applied for quantitation of the studied drug in its pure form with mean percentage recoveries of 100.47 ± 1.12 , 100.17 ± 1.21 and 99.23 ± 1.26 for Methods I, II and III, respectively. Moreover the proposed methods were successfully applied for determination of ALD in different tablets. Proposals of the reactions pathways have been postulated.

Conclusion: The proposed spectrophotometric methods provided sensitive, specific and inexpensive analytical procedures for determination of the non-chromophoric drug alendronate either per se or in its tablet dosage forms without interference from common excipients.

Background

Bisphosphonates is the name given to a group of drugs characterized by a geminal bisphosphonate bond [1]. From the clinical point of view, bisphosphonates are used for the treatment of osteoporosis, bone metastasis, Paget's disease, hypocalcaemia associated with malignancy and other conditions that feature bone fragility [2].

Among bisphosphonates, one of the most popular first-line drugs is alendronate sodium trihydrate (ALD). ALD is designated chemically as (4-amino-1-hydroxybutylidene) biphosphonic acid monosodium salt trihydrate [3] (Figure 1). The two phosphonic groups per molecule lend a strongly ionic character to ALD and increased polarity. Additionally, ALD does not possess an appreciable chromophore; hence its determination by ordinary spectrophotometric methods is not possible.

ALD is the subject of a monograph in both the British pharmacopoeia (BP) [3] and the United States Pharmacopoeia (USP) [4]. The BP [3] describes an HPLC method with refractive index detection for determination of ALD in its pure form, while The USP [4] recommends an HPLC method with UV-detection after derivatization with 9-fluorenylmethyl chloroformate for its determination, whether in its pure form and in tablets. Several methods have been presented in the literature for the determination of ALD. These include spectrophotometry through complex formation [5,6], oxidation with ceric (IV) sulfate [7] and derivatization of its free primary amino group [7,8]. Also the molybdovanadate approach was employed for the determination of ALD in tablets by spectrophotometry [9]. Furthermore, titrimetry [10-12], liquid chromatography with different modes of detection [9,13-23], capillary electrophoresis [24-26] and stopped flow spectrofluorimetric methods [27] have been applied for the determination of ALD.

Since ALD has no functional group that enables absorption in the UV-visible region, so we decided to analyze the drug through derivatization reactions. In this approach, two different labeling agents, namely; 4-chloro-7-nitrobenzo-2-oxa-1,3-diazole (NBD-Cl) and 2,4-

dinitrofluorobenzene (DNFB, Sanger's reagent) have been used in derivatization reactions based on their reaction with the free primary amino group of ALD.

Both reagents are well known to react with primary and secondary amines forming stable condensation colored products [28]. NBD-Cl, as an electroactive halide reagent, was first introduced as an analytical reagent for the determination of some amines and amino acids. In recent reports, NBD-Cl was further used as a chromogenic reagent for the determination of some primary and secondary amines [29-34]. DNFB has been applied as a chromophore reactant in the spectrophotometric determination of some compounds. The reaction of DNFB with amines proceeds very slowly at room temperature. Such reaction could be catalyzed by heating [33,35,36] or by addition of micellar solution [37-39].

The aim of the present study was to optimize the reaction of ALD with both NBD-Cl and DNFB. The reaction of ALD with DNFB was enhanced by either heating at 60°C or by the addition of cetrimide as a cationic surfactant to the reaction mixture. The applicability of the developed methods was evaluated through the determination of ALD in pure form and tablet formulations.

Experimental

Instruments

-A Shimadzu UV-Visible 1601 PC spectrophotometer (Kyoto, Japan) was used for spectrophotometric measurements (P/N 206-67001). The recording range was 0-1.0

-A consort NV P901 digital pH meter (Belgium) calibrated with standard buffers was used for checking the pH of the buffer solutions used.

Reagents and materials

All the reagents used were of analytical grade and distilled water was used throughout the work.

-Amriya Pharm. Ind. CO. (Alexandria, Egypt) kindly supplied a pure sample of alendronate sodium trihydrate (with a purity of 100.55% as determined by the comparison method [7]) (Batch # AAS0400010).

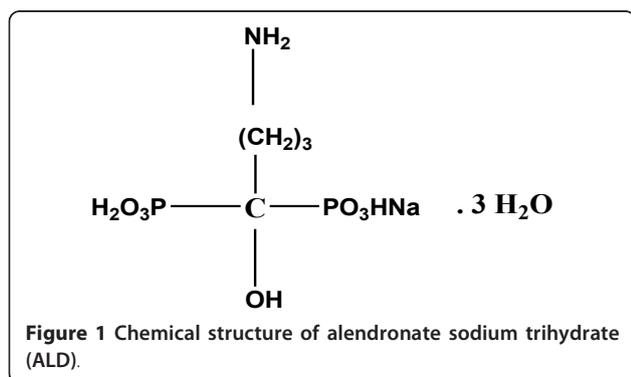

-NBD-Cl (Aldrich Chemical Co. Ltd., USA) was freshly prepared as 0.2% (w/v) methanolic solution.

-DNFB (Fluka chemica, USA) solution was freshly prepared as 0.3% (v/v) in methanol, for both methods II and III.

-Cetyltrimethylammonium bromide (cetrimide) was obtained from Merck (Darmstadt, Germany), 1% (w/v) aqueous solution was prepared.

-Sodium dodecyl sulphate (SDS, 95%) was obtained from Winlab (Middlesex, England). 1% (w/v) aqueous solution was prepared.

-Methanol, concentrated hydrochloric acid, sodium hydroxide, boric acid and tween-80 (1%w/v aqueous

solution) were purchased from El-Nasr Pharm. Chem. Co. (ADWIC), Abu Zabaal, Egypt.

-Borate buffer solutions (0.2 M) were prepared by mixing appropriate volumes of 0.2 M boric acid and 0.2 M NaOH and adjusting the pH to 10.0, 10.5 and 10.7 using a pH meter [40].

-The following tablets containing the drug were purchased from local pharmacies:

- Osteonate[®] tablets (batch # 060181) labeled to contain 10 mg alendronic acid equivalent to 13.05 mg alendronate sodium trihydrate, product of the Egyptian Co. For Chemicals and Pharmaceuticals (ADWIA) S.A. E, 10th of Ramadan City, Egypt.
- Alendex[®] tablets (batch # 6038) labeled to contain 40 mg of alendronic acid equivalent to 52.2 mg alendronate sodium trihydrate, product of Uni Pharma Co., Al Obour City, Cairo, Egypt.

Standard solutions

Standard solutions of ALD were prepared by dissolving 20.0, 40.0 and 30.0 mg of ALD in 100 mL distilled water for methods I, II and III, respectively. These solutions were stable for at least 10 days when stored in the refrigerator. Working solutions were obtained by appropriate dilution.

General recommended procedures

Construction of calibration graphs

i. Method I To a set of 10-mL volumetric flasks, aliquot volumes containing the drug in the working concentration range of 1.0-20.0 µg/mL were quantitatively transferred. To each flask 1 mL of borate buffer (pH 10.7) followed by 1.2 mL of NBD-Cl solution (0.2% w/v) were added and mixed well. The solutions were heated in thermostatically controlled water bath at 70°C for 25 min. The reaction was stopped by cooling under tap water, then 0.2 mL of concentrated HCl was added and the solutions were made up to volume with methanol. The absorbance was measured at 472 nm against a reagent blank. The calibration graph was constructed by plotting the absorbance versus the final concentration of the drug (µg/mL). Alternatively, the corresponding regression equation was derived.

ii. Method II To a set of 10-mL volumetric flasks, aliquot volumes containing the drug over the working concentration range of 4.0-40.0 µg/mL were quantitatively transferred. To each flask 1 mL of borate buffer (pH 10.5) followed by 1.2 mL of DNFB solution (0.3% v/v) were added and mixed well. The solutions were heated in thermostatically controlled water bath at 60°C for 15 min. The reaction was stopped by cooling under tap water, then 0.2 mL of concentrated HCl was added and the flasks

were made up to volume with water. The absorbance was measured at 378 nm against a reagent blank. The absorbance was plotted versus the final concentration of the drug (µg/mL) to obtain the calibration graph. Alternatively, the corresponding regression equation was derived.

iii. Method III To a set of 10-mL volumetric flasks, aliquot volumes containing the drug over the working concentration range of 1.5-30.0 µg/mL were quantitatively transferred. A volume of 1 mL of 0.2 M borate buffer (pH 10.0) was added to each flask followed by 0.8 mL of 1% w/v cetrimide solution and 1 mL of DNFB solution (0.3% v/v). The solutions were mixed well and left at room temperature for 5 min before the addition of 0.2 mL of concentrated HCl to all the flasks. The volumes were completed using distilled water. The absorbance was measured at 374 nm against a reagent blank. The absorbance was plotted versus the final concentration of the drug (µg/mL) to obtain the calibration graph. Alternatively, the corresponding regression equation was derived.

Assay procedure for tablets

Ten tablets were accurately weighed, finely powdered and mixed well. A portion of the powder equivalent to 20.0 mg (method I), 40.0 mg (method II) and 30.0 mg (method III) of ALD was transferred into 100-mL volumetric flasks, about 80 mL distilled water was added to each flask and they were sonicated for 15 min. The volume was completed with water, mixed and filtered. Aliquots covering the working concentration ranges cited in Table 1 were transferred into 10-mL volumetric flasks. The procedures described under "Construction of calibration graphs" were followed adopting any of the three methods. The nominal contents of the tablets were calculated using the corresponding regression equation.

Results and discussion

Method I

ALD is a primary aliphatic amino derivative that was found to react with NBD-Cl with the formation of a yellow adduct. Under the described experimental conditions, the yellow adduct has a characteristic absorption spectrum with maximum absorbance at 472 nm as shown in Figure 2.

Study of experimental parameters

The experimental conditions were studied by varying each parameter individually and noting its effect on the absorbance of the product.

i. Effect of pH and volume of buffer The pH dependence of the system was studied over the range of 7.0-11.0 using 0.2 M borate buffer. Maximum absorption intensity was obtained at pH 10.7 ± 0.2. Therefore, pH 10.7 was chosen as the optimum pH for such study (Figure 3). Maximum absorption intensity was obtained upon using 1 ± 0.5 mL of the buffer solution (Figure 4). Other buffers

Table 1 Analytical performance data for the proposed methods

having the same pH value such as Britton Robinson buffer and phosphate buffer were attempted and compared with 0.2 M borate buffer. Borate buffer was found to be superior to others as revealed by the high absorption intensity. This different response to different buffers may be attributed to the slow rate of hydrolysis of NBD-Cl to NBD-OH

in borate buffer. This result is in agreement with that of Miyano H. et al. [41].

ii. Effect of concentration of NBD-Cl solution The influence of NBD-Cl concentration was studied using different volumes of 0.2% w/v solution of the reagent. It was found that increasing volumes of the reagent produce a

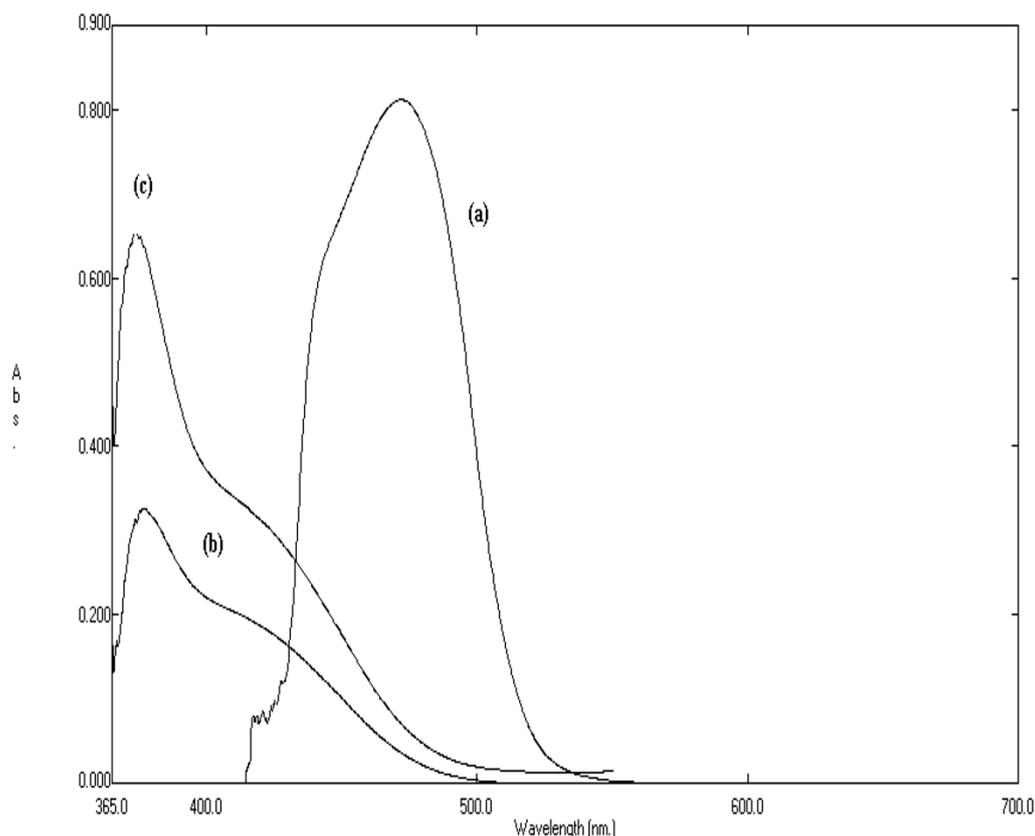

Figure 2 Absorption spectra of the reactions products: (a) ALD (20 $\mu\text{g/mL}$) with NBD-Cl(Method I), (b) ALD (20 $\mu\text{g/mL}$) with DNFB (Method II), (c) ALD (18 $\mu\text{g/mL}$) with DNFB (Method III).

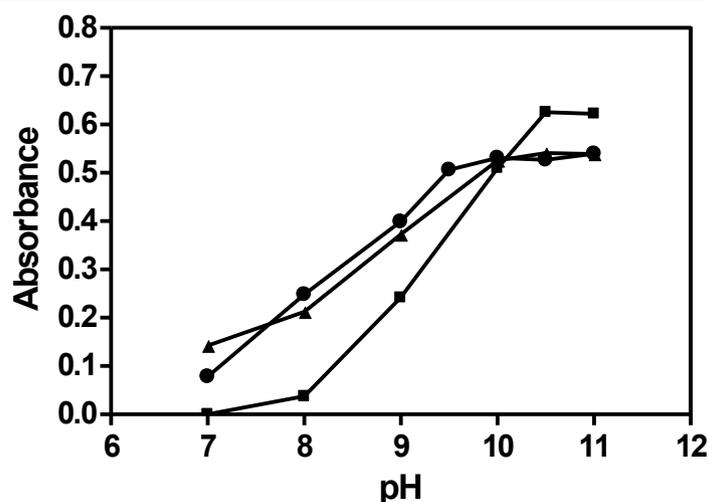

Figure 3 Effect of the pH of 0.2 M borate buffer on the reaction of: ■ ALD (15 µg/mL) with NBD-Cl, ▲ ALD (40 µg/mL) with DNFB (method II), ● ALD (15 µg/mL) with DNFB (method III).

proportional increase in the absorption intensity up to 1 mL. However, no further increase in the absorption intensity was observed upon increasing the volume of the reagent up to 1.5 mL, after which further increase produced a gradual decrease in the absorption intensity. Therefore, 1.2 mL of 0.2% w/v NBD-Cl solution was chosen as the optimal volume of the reagent (Figure 5). The absorption value of the hydrolysis product of NBD-Cl, namely, 4-hydroxy-7-nitro-benzo-2-oxa-1,3-diazole (NBD-OH), is quenched by decreasing the pH of the reaction medium to less than 1 by adding 0.2 mL of concentrated HCl. Therefore, acidification of the reaction mixture prior to measurement of the absorbance value remarkably decreased the background absorbance due to the formation of NBD-OH without affecting the drug-reagent adduct, hence the sensitivity was increased [42].

iii. Effect of heating temperature and heating time Preliminary studies revealed that the reaction rate was very slow at room temperature. In this study, the reaction was performed at different temperatures for various time intervals. As it is seen in Figure 6A, the reaction was completed at 70°C within 25 ± 5 min. Increasing the temperature to 80°C resulted in an apparent decrease in the absorption intensity.

iv. Effect of diluting solvent The effect of diluting solvent was tested using different solvents viz water, methanol, acetone, acetonitrile, dimethylformamide and isopropanol. Using water as diluting solvent gives the highest absorbance value. However, the reproducibility upon using this diluting solvent was found to be adversely affected. Of all the diluting solvents studied, methanol was chosen as the best one since it gave reasonable absorption intensity with maximum product stability.

v. Effect of time on the stability of the formed adduct

Regarding the stability of the produced derivative, it was found to be stable at room temperature for approximately 1 h after which it faded slowly.

Method II

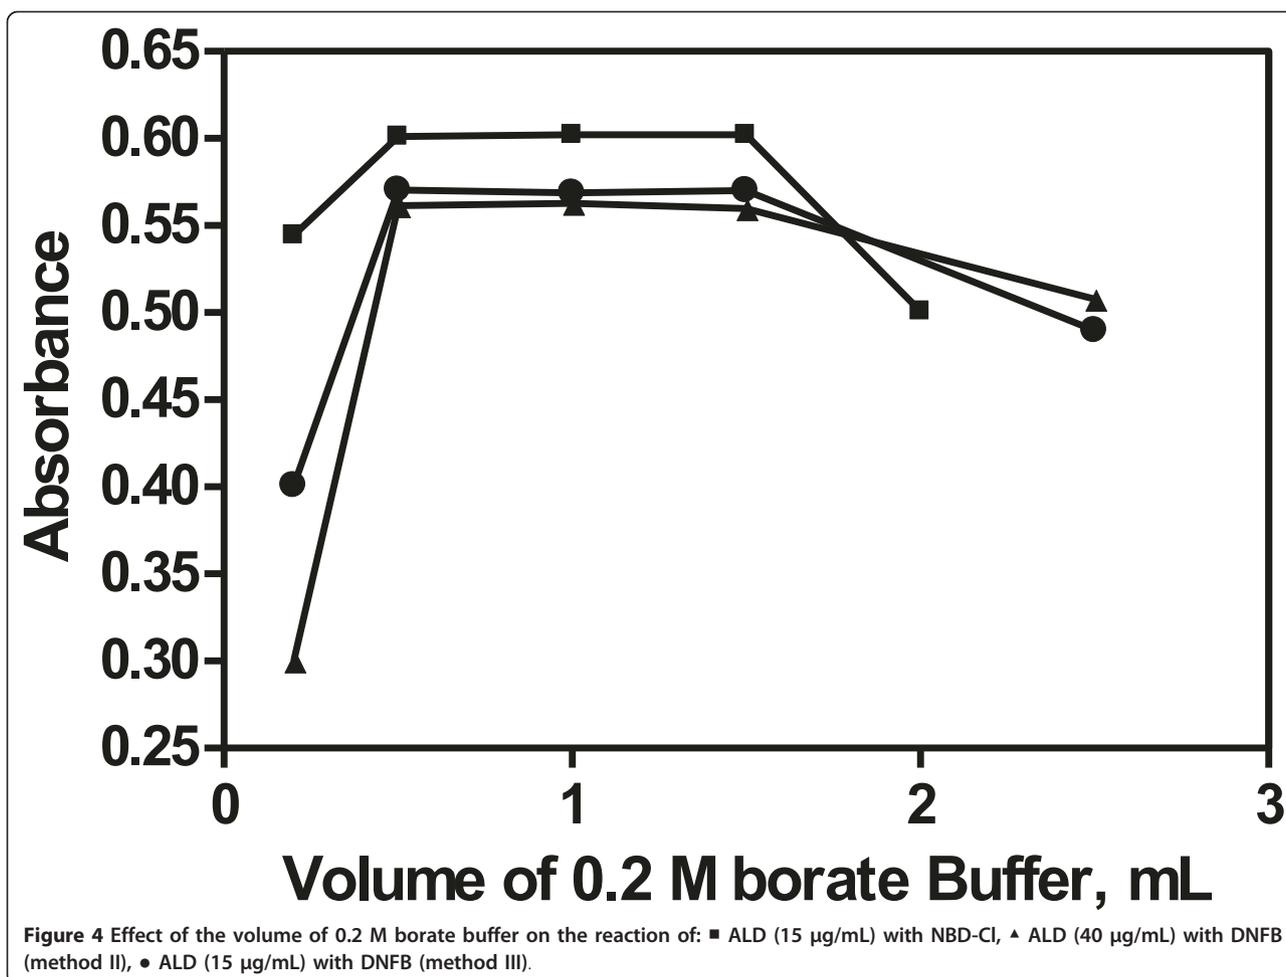

The analytical applications of 2,4-dinitrofluorobenzene (DNFB) for the assay and characterization of specific functional groups such as primary and secondary amines, phenols, thiols and imidazoles have been established by Connor [43]. In the present work, DNFB reacts through a nucleophilic aromatic substitution reaction with the primary aliphatic amino group of ALD in aqueous alkaline medium. The reaction between ALD and DNFB is very slow at room temperature and required heating to speed it up. A yellow colored product peaking at 378 nm is produced (Figure 2).

Study of experimental parameters

The experimental conditions for the derivatization reaction were optimized by the univariate method (changing one parameter at each step).

i. Effect of pH and volume of buffer The reaction was investigated over the pH range of 7.0-11.0 using 0.2 M borate buffer. The product showed the highest absorption in buffer of pH 10.5 ± 0.5 (Figure 3). Therefore, pH 10.5 was selected as the optimum pH for such reaction. It was found that increasing the volume of the buffer produces a corresponding increase in the absorbance value of the reaction product up to 0.5 mL, and it remained constant up to 1.5 mL (Figure 4). Therefore, 1 mL was chosen as the optimum buffer volume.

ii. Effect of concentration of DNFB solution The influence of the concentration of DNFB was studied using

different volumes of 0.3% v/v solution of the reagent. It was found that increasing volumes of the reagent produce a proportional increase in the absorption intensity up to 1 mL. However, no further increase in the absorption intensity was observed upon increasing the volume of the reagent up to 1.5 mL, after which further increase produces a gradual decrease in the absorption intensity. Therefore, 1.2 mL of 0.3% v/v DNFB solution was chosen as the optimal volume of the reagent (Figure 5). To remove the excess reagent interference in the absorbance measurement of the reaction product, this excess was acid-hydrolyzed to colorless 2,4-dinitrophenol by adding 0.2 mL of concentrated HCl allowing the measurement of ALD-DNFB derivative which remains stable.

iii. Effect of heating temperature and heating time In order to obtain the highest and most stable absorbance, the effect of the reaction time and heating temperature was investigated (Figure 6B). It was found that the reaction proceeds very slowly at room temperature. A gradual increase in the heating temperature produced a significant increase in the absorbance of the reaction

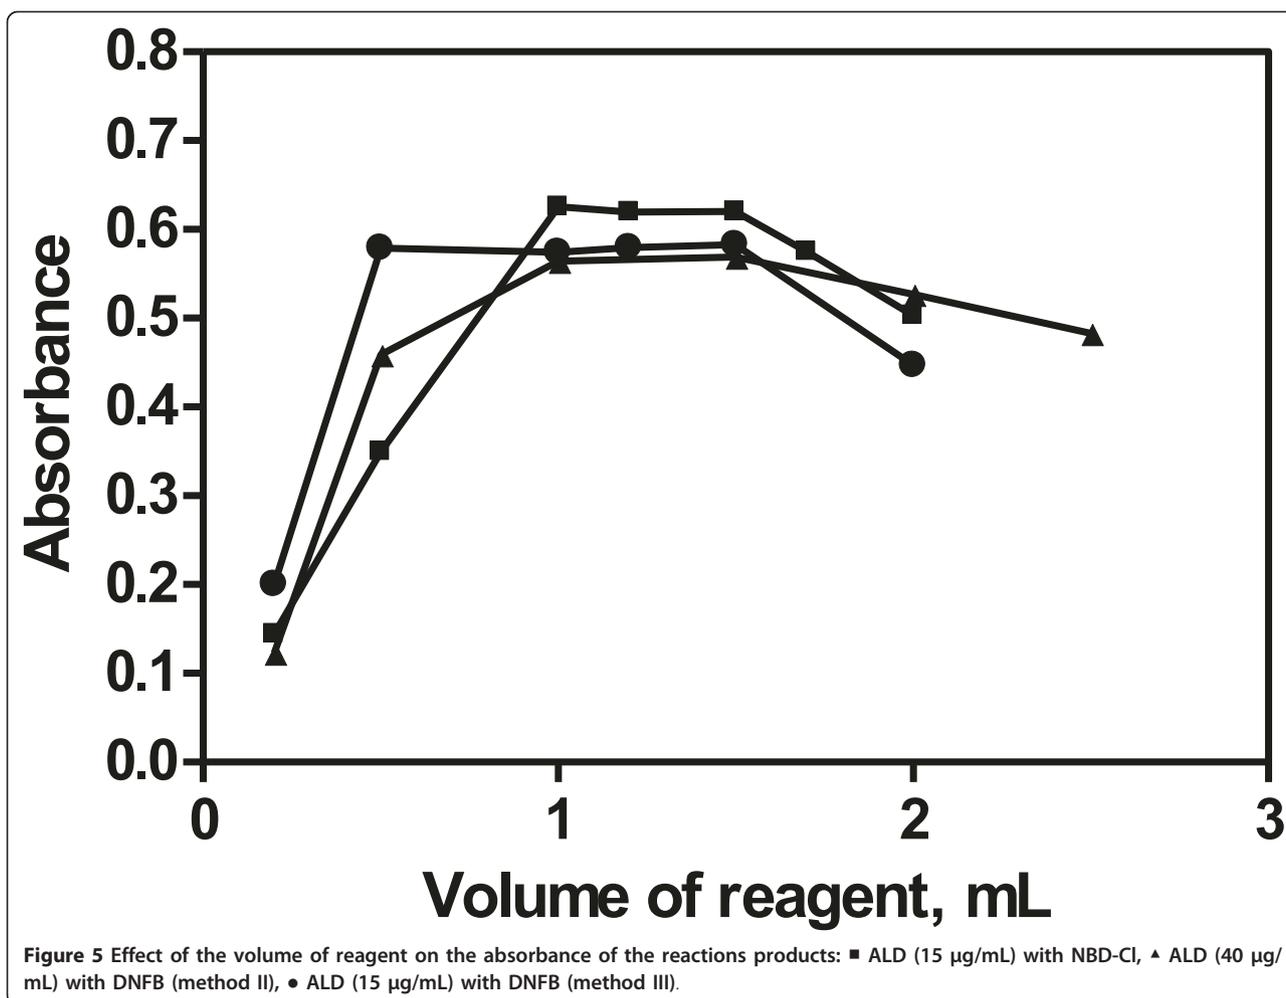

product up to 70°C. Heating at 80°C resulted in precipitation of the reagent. Therefore, the reaction was carried out at 60°C for 15 min, which was adequate for complete color development.

iv. Effect of diluting solvent The effect of different diluting solvent was tested using water, methanol, acetone, acetonitrile, dimethylformamide, dimethylsulfoxide and isopropanol. Using water as diluting solvent gives highest absorbance value and best peak shape. Additionally, the spectrum for ALD-DNFB in this solvent was found to be shifted about 10 nm toward higher wavelength compared to those in methanol, acetone, isopropanol and acetonitrile. On the other hand, dilution with dimethylformamide and dimethylsulfoxide resulted in high blank reading. Finally, water was chosen as the best diluting solvent.

v. Effect of time on the stability of the formed adduct The reaction product was found to be stable for at least 60 min at room temperature.

Method III

According to the literature, the reaction of DNFB with amines could be performed at room temperature or

even at low temperature and in a short time through micellar catalysis. It was

found that the micellar catalysis is useful not only in speeding up the slow reaction of DNFB with ALD, and thus adapting the time scale of the experiment, but also in softening the experimental conditions required to carry out the reaction, e.g. reducing the temperature and the time for completion of the reaction. In addition, the increase in the rate of the reaction is accompanied by an increase in the apparent molar absorptivity, and therefore the sensitivity and reliability of the procedure adapted.

Study of experimental parameters

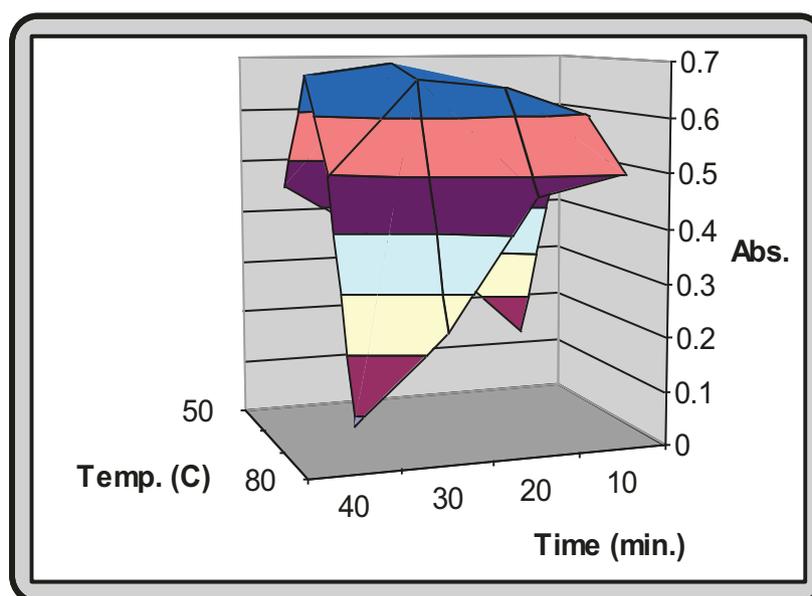

The experimental conditions for the derivatization reaction were optimized by the univariate method.

i. Effect of pH and volume of buffer The reaction was investigated over the pH range of 7.0-11.0 using 0.2 M borate buffer. It was found that increasing the pH resulted in a corresponding increase in the absorbance of the reaction product up to pH 9.5 after which it remained constant. Therefore, pH 10.0 was chosen as the optimal pH throughout this study (Figure 3). It was

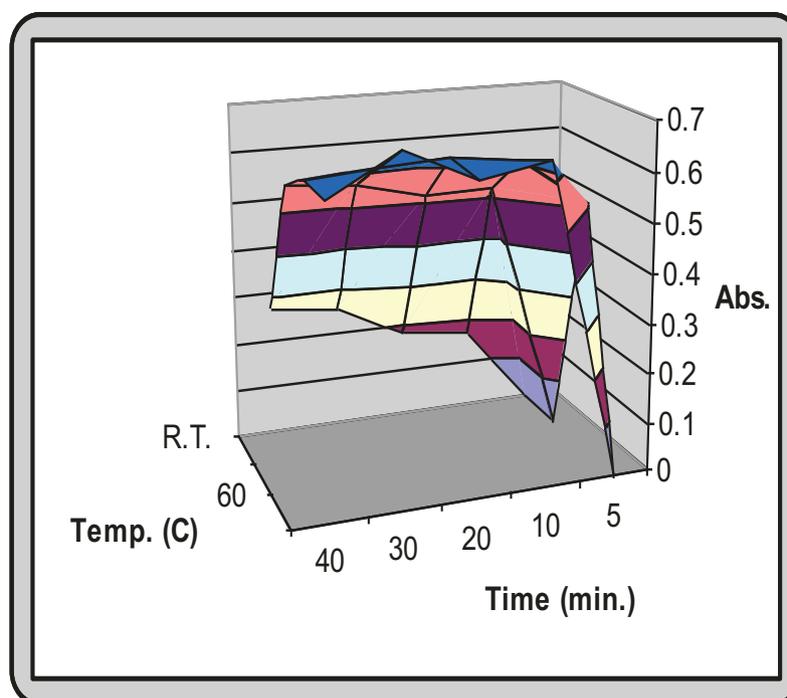

found that increasing the volume of the buffer produces a corresponding increase in the absorbance value of the reaction product up to 0.5 mL, and it remained constant up to 1.5 mL (Figure 4). Therefore, 1 mL was chosen as the optimum buffer volume.

ii. Effect of concentration of DNFB solution The influence of the concentration of DNFB was studied using different volumes of 0.3% v/v solution of the reagent. It was found that increasing volumes of the reagent produce a proportional increase in the absorption intensity up to 0.5 mL. However, no further increase in the absorption intensity was observed upon increasing the volume of the reagent up to 1.5 mL, after which further increase produces a gradual decrease in the absorption intensity. Therefore, 1.0 mL of 0.3% v/v DNFB solution was chosen as the optimum volume of the reagent (Figure 5). To remove the excess reagent interference in the absorbance measurement of the reaction product, 0.2 mL of concentrated HCl was added.

iii. Effect of concentration of cetrimide The optimal cetrimide concentration required to catalyze the reaction

(A)

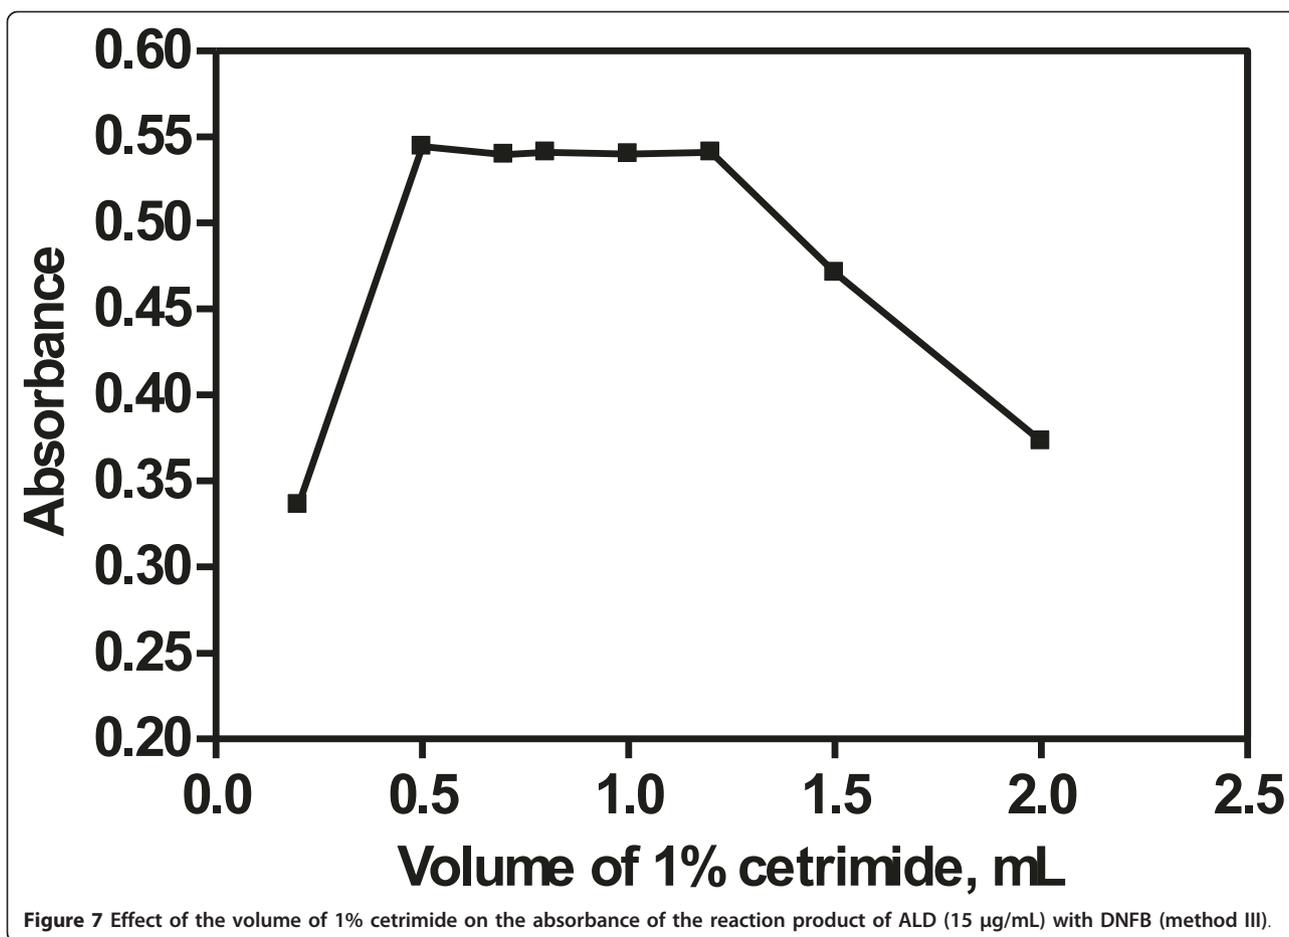

(B)

Figure 6 Effect of the heating time on the proposed reactions at different temperature settings. (A) ALD (15 µg/mL) with NBD-Cl, (B) ALD (40 µg/mL) with DNFB (method II).

of ALD with DNFB was determined by adding increasing volumes of 1% w/v cetrimide solution to the reaction mixture. It was found that 0.5-1.2 ml of 1% cetrimide solution was suitable to develop the absorbance to its

maximum intensity. The absorbance intensity decreased with further increase in the volume of cetrimide solution. 0.8 mL of 1% w/v aqueous cetrimide solution was chosen as optimal volume throughout this work (Figure 7).

About 5.5-folds increase of the sensitivity was obtained in presence of cetrimide relative to that in the non-micellar aqueous medium at room temperature for longer time (30 min) (Figure 8).

When cetrimide was replaced by anionic surfactant (SDS) or nonionic surfactant (tween 80) no enhancement of the sensitivity was observed relative to the non-micellar medium.

iv. Effect of diluting solvent The effect of diluting solvents other than water such as methanol, acetone, acetonitrile, dimethylformamide, dimethylsulfoxide and isopropanol was also investigated to obtain the maximum color intensity. It was found that water, isopropanol and acetonitrile are of similar effect. Meanwhile, methanol, acetone, dimethylformamide and dimethylsulfoxide slightly decreased the color intensity. Water was selected as the optimal diluting solvent.

v. Effect of time on the formation and stability of the formed adduct Maximum color development was obtained within 5 min of mixing the reactants (Figure 8), and was stable for at least 60 min thereafter.

A summary for the optimization study of the variables affecting the three proposed methods is given in Table 2.

Validation of the proposed methods

The validity of the proposed methods was tested regarding linearity, range, limit of quantitation, limit of detection, accuracy, precision, robustness and specificity according to ICH Q2(R1) recommendations [44].

Linearity and range

The calibration graphs obtained by plotting the values of the absorbance versus the final concentrations (µg/mL) were found to be rectilinear over the concentration ranges cited in Table 1. The proposed methods were evaluated for the accuracy as percent relative error (% Er) and the precision as percent relative standard deviation (% RSD) (Table 1). The validity of the proposed methods were proven by statistical evaluation of the regression line, using the standard deviation of the residuals ($S_{y/x}$), the standard deviation of the intercept (S_a) and standard deviation of the slope (S_b). The results are abridged in Table 1. The small values of the figures indicate low scattering of the points around the calibration line.

Limits of quantitation and limits of detection

The limits of quantitation (LOQ) were determined by establishing the lowest concentrations that can be

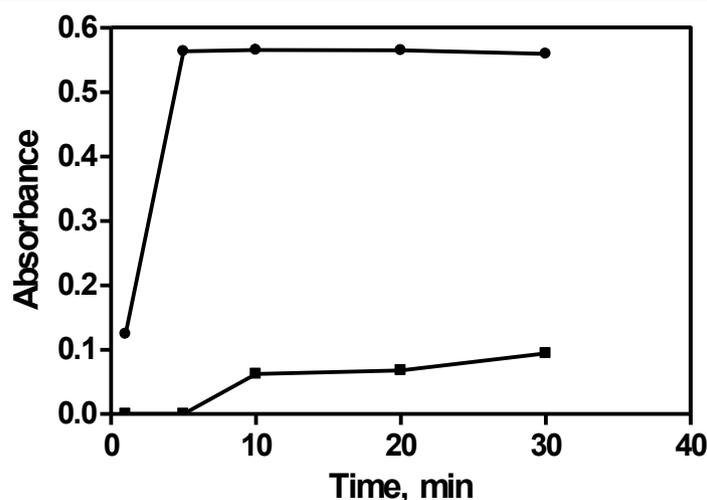

Figure 8 Effect of the time on the reaction of ALD (15 µg/mL) with DNFB at room temperature: ● in presence of 0.8 mL of 1% w/v cetrimide solution. ■ in absence of cetrimide.

measured according to ICH Q2 (R1) recommendation [44] below which the calibration graph is non linear. The limits of detection (LOD) were determined also by evaluating the lowest concentrations of the analytes that can be readily detected. The results are summarized in Table 1.

LOQ and LOD were calculated according to the following equations [44]:

$$\text{LOQ} = 10 S_a/b$$

$$\text{LOD} = 3.3 S_a/b$$

Where S_a is the standard deviation of the intercept of regression line, and b is the slope of the regression line.

The obtained sensitivities were comparable to those reported for other analytical techniques used for determination of ALD.

Table 2 Assay parameters for the determination of ALD by the three proposed methods

| parameter | Method I | Method II | Method III |
|--------------------------------|------------|-------------|-------------|
| Standard conc. (µg/mL) | 200 | 400 | 300 |
| Borate buffer pH | 10.7 ± 0.2 | 10.5 ± 0.5 | 10.0 ± 0.5 |
| Borate buffer volume (mL) | 1 ± 0.5 | 1 ± 0.5 | 1 ± 0.5 |
| Reagent conc. | 0.2% w/v | 0.3% v/v | 0.3% v/v |
| Reagent volume (mL) | 1.2 ± 0.2 | 1.2 ± 0.2 | 1.0 ± 0.5 |
| Temperature (°C) | 70 ± 5 | 60 ± 5 | Room temp. |
| Time (min) | 25 ± 5 | 15 ± 5 | 5 |
| Stability of the product (min) | 60 | At least 60 | At least 60 |
| Diluting solvent | methanol | water | water |
| λ_{max} (nm) | 472 | 378 | 374 |

Accuracy

To test the validity of the proposed methods they were applied to the determination of pure sample of ALD over the concentration ranges cited in Table 3. The results obtained were in good agreement with those obtained using the comparison spectrophotometric method. Student t -test and the variance ratio F -test [45] revealed no significance differences between the performance of the proposed and comparison methods regarding the accuracy and precision, respectively (Table 3). The spectrophotometric comparison method [7] depends on determination of the studied drug through oxidation with ceric sulfate in 0.5 M sulfuric acid and subsequent measurement of the excess unreacted cerium (IV) sulfate at 320 nm.

Precision

i. Repeatability The repeatability was tested by applying the proposed methods for the determination of three concentrations of ALD in pure form for three successive times. The results are presented in Table 4.

ii. Intermediate precision Intermediate precision was tested by repeated analysis of ALD in pure form using the concentrations shown in Table 4 over a period of three successive days. The results are also summarized in Table 4.

Robustness

The robustness of the proposed methods is demonstrated by the constancy of the absorbance with the deliberated minor changes in the experimental parameters such as change in pH (10.7 ± 0.2), change in the volume of buffer (1 ± 0.5 mL), change in the volume of 0.2%w/v NBD-Cl (1.2 ± 0.2), change in the heating temperature (70 ± 3°C) and change in the heating time, 25 ± 5 min for method I. Meanwhile, for method II these changes include; change in pH (10.5 ± 0.5), change in the volume of the buffer

Each result is the average of three separate determinations

*Values between brackets are the tabulated t and F values, at $p = 0.05$ [45]

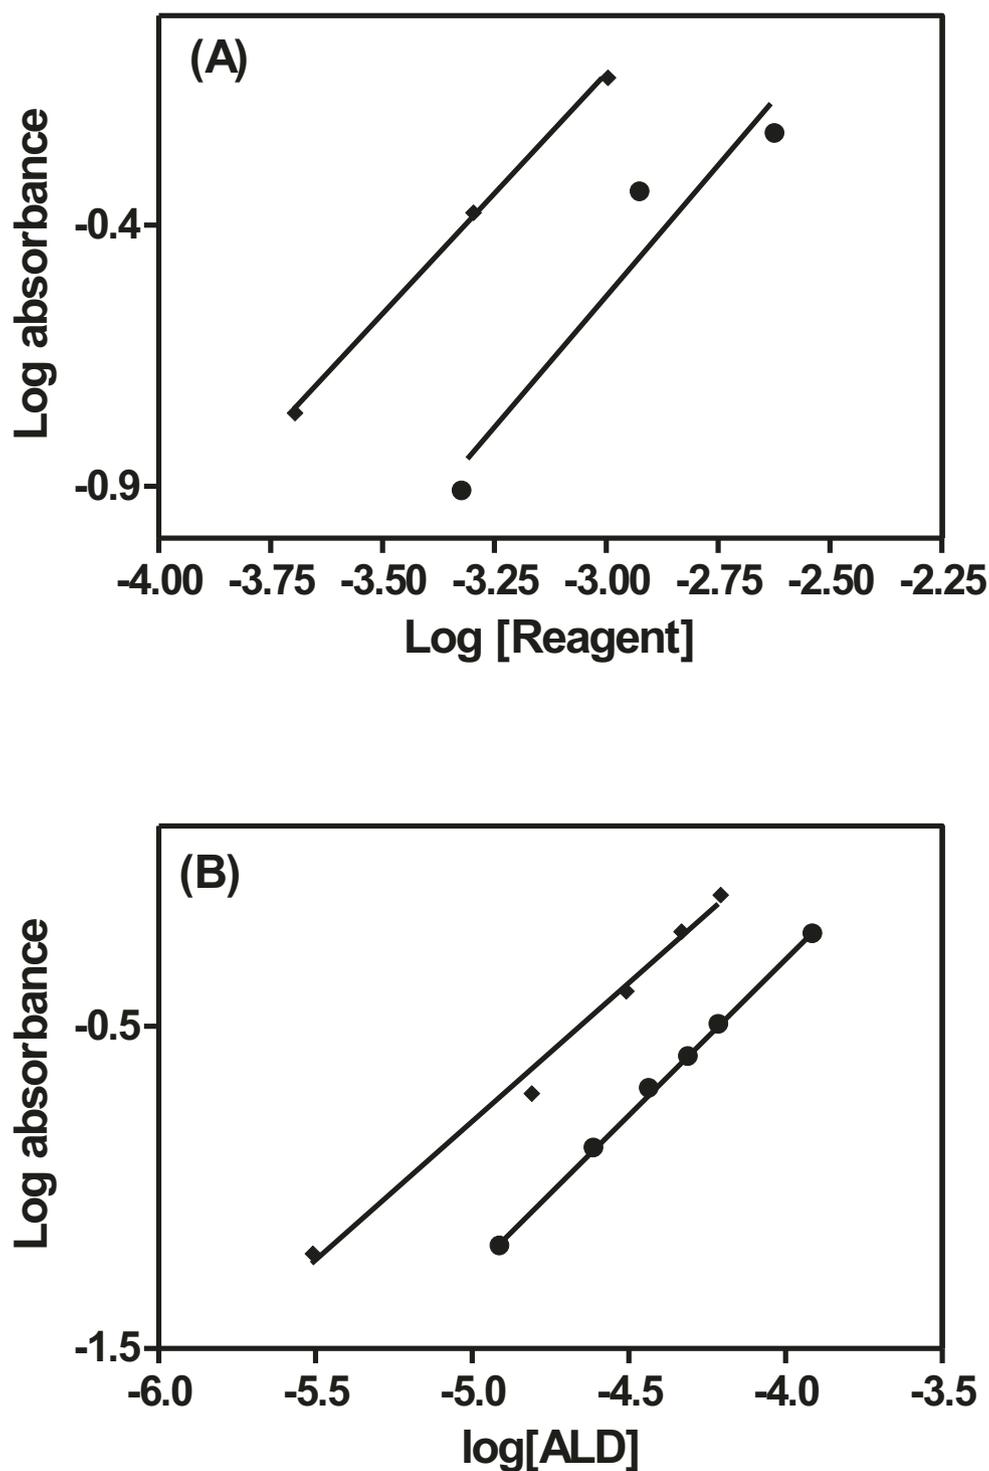

Figure 9 Limiting logarithmic plots for the molar reactivity of ALD with the two proposed reagents: (A) log A vs log [reagent] with [ALD] kept constant; (B) log A vs log [ALD] with [reagent] kept constant; Where, \blacksquare Method I (NBD-Cl method), and \bullet Method II (DNFB method).

(1 ± 0.5 mL), change in the volume of 0.3% v/v DNFB (1.2 ± 0.2 mL), change in the heating temperature ($60 \pm 5^\circ\text{C}$) and change in the heating time (15 ± 5 min). For

method III these changes include; change in pH (10.0 ± 0.5), change in the volume of the buffer (1 ± 0.5 mL), change in the volume of 0.3% v/v DNFB solution ($1.0 \pm$

0.5 mL), and change in the volume of 1% w/v cetrimide solution (0.8 ± 0.3 mL). These minor changes that may take place during the experimental operation didn't affect the absorbance of the reactions products.

Specificity

The specificity of the methods was investigated by observing any interference encountered from the common tablet excipients. These excipients did not interfere with the proposed methods.

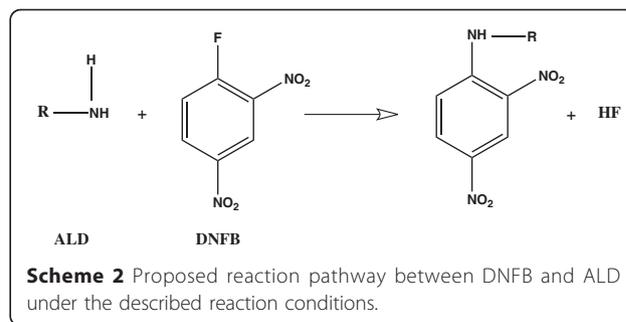

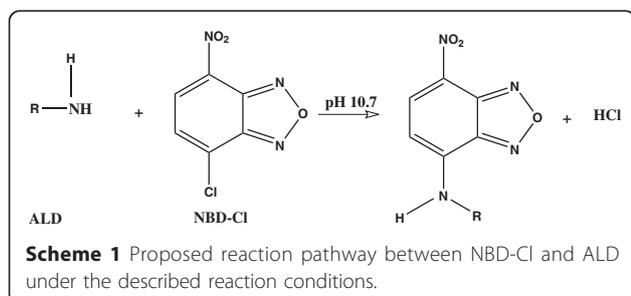

Pharmaceutical applications

The proposed methods were successfully applied to determine the studied drug in its pharmaceutical preparations. The results obtained were statistically compared to those of a reported method [7] by student's *t*-test and variance ratio *F*-test as shown in Table 5. The experimental values of *t* and *F* did not exceed the theoretical values, indicating lack of significant difference between the compared methods.

Molar ratio and mechanism of the proposed reactions

The stoichiometry of the two reactions was studied adopting the limiting logarithmic method [46]. For the two reactions, two straight lines were obtained using increasing concentrations of the reagent while keeping the concentration of the drug constant and using increasing concentrations of the drug while keeping the concentration of the reagent constant. Plots of log absorbance versus log [NBD-Cl] and log [ALD] gave two straight lines, the slopes of which were 0.9208/0.8597, respectively (Figure 9). Hence, it is concluded that the reaction proceeds in the ratio of 1:1, confirming that one molecule of the drug condenses with one molecule of NBD-Cl.

Method II was applied for the determination of the stoichiometry of the reaction of ALD and DNFB. Plots of log absorbance versus log [DNFB] and log [ALD] gave straight lines; the values of their slopes were 0.9157 and 0.9666, respectively (Figure 9). Hence, it is concluded that the reaction proceeds in the ratio of 1:1, confirming that one molecule of the drug condenses with one molecule of DNFB.

Based on the observed molar ratios, proposed reaction pathways are given in schemes 1 and 2, respectively.

The micellar catalytic effect of the cationic surfactant, cetrimide, on the reaction of ALD with DNFB may be explained on the basis of electrostatic interactions. ALD features 5 negative charges, so it will be electrostatically attracted to the oppositely charged micelles of cetrimide, and thereby brought closer to DNFB reagent that's preferentially solubilized by the micelles, thus contributing to acceleration of the reaction [47].

Critical comparison of the three developed methods

The critical comparison of the three developed spectrophotometric methods for the determination of ALD leads to the following advantages/disadvantages:

1. All methods are sufficiently sensitive and selective for the determination of the analyte in its pharmaceutical formulations.
2. The linearity and sensitivity are best for Method I. Meanwhile, method I and method III offer the widest determination range (1.0-20.0 $\mu\text{g/mL}$ for method I and 1.5-30.0 $\mu\text{g/mL}$ for method III).
3. The third method offers the shortest reaction time (5 min)
4. The second and third methods employ simpler diluting solvent (water versus methanol for third method) providing cost effectiveness

Other techniques such as capillary electrophoresis and HPLC may also give good results but, because of the low cost and ease of carrying out the spectrophotometric methods, the

proposed procedures are likely to be very suitable for the quality control of ALD in tablet dosage form.

Conclusion

The proposed spectrophotometric methods provided sensitive, specific and inexpensive analytical procedures for determination of the non-chromophoric drug alendronate either per se or in its tablet dosage forms without interference from common excipients. Moreover, the developed methods are less time-consuming and do not require elaborate treatments associated with chromatographic

methods. These attributes, in addition to the satisfactory sensitivity and reproducibility as well as the convenience and simplicity, make the three proposed methods suitable for routine analysis in quality control laboratories.

Authors' contributions

MIW supervised the whole study, M.E. -SM participated in supervision, ME participated in the assay design, results discussion, and preparing the manuscript. RNE suggested the idea of the assay, conducted practical work and prepared the draft version of the manuscript. All authors read and approved the final manuscript.

Competing interests

The authors declare that they have no competing interests.
